#### Introduction

The Town of Lakeview, Oregon, provides drinking water to residents within its urban growth boundary. The Town's sources include Wells No. 1, 2, 6, 7, 8, and 9 (herein referred to as Town Wells) that pump into a common line, one isolated well (North Well), and a spring. Water quality varies from each source, but collectively the Town's drinking water has issues with taste, odor, and color. These issues can generally be attributed to National Secondary Drinking Water Regulations (NSDWRs) water quality constituents including sulfates, iron, and manganese, in addition to hydrogen sulfide, which is not regulated by the U.S. Environmental Protection Agency (EPA). Secondary contaminants have aesthetic, cosmetic, and technical effects to water systems but do not present a risk to human health. Arsenic is also present in the Town's groundwater sources, more significantly in the North Well. As a National Primary Drinking Water Regulations (NPDWRs) contaminant, arsenic is regulated due to its hazard to human health. The North Well has arsenic concentrations above the maximum contaminant level (MCL) regulated by the EPA of 0.010 milligrams per liter (mg/L). Currently, the North Well is not used but may eventually be needed for additional production to meet demands as the Town grows. The Town's other wells have lower levels of arsenic, which have varied through time but are generally less than the MCL. The purpose of this Technical Memorandum (TM) is to evaluate available treatment technologies commonly used to remove arsenic, iron, and manganese from drinking water, provide a lifecycle cost

Sound Solutions

Scott Langum September 9, 2022 Page -2-

analysis for viable alternatives, and provide the Town with direction as to the next steps in the planning, procurement, and implementation of the preferred alternative.

#### Background

Anderson Engineering and Surveying, Inc., prepared a Water System Master Plan (WSMP) for the Town in 2019. The WSMP outlined water quality issues and proposed mitigation alternatives to improve water quality, including constructing separate filtration systems at each well, constructing a combined water treatment facility (WTF), and installing a transmission line from the North Well to the combined WTF. Prior to the preparation of this TM, the Town further refined viable alternatives to two options. The first is to construct a WTF at the North Well to remove arsenic and to construct a second WTF for the Town Wells to remove iron and manganese. The second alternative is to construct a transmission line from the North Well to the Town Wells and to construct a single WTF to remove iron, manganese, and arsenic from the combined sources. These alternatives are referred to further in this TM as Alternatives A and B, respectively, and are evaluated for cost, operation and maintenance, flexibility, and operator skill and attention.

To adequately evaluate the cost and operation of available treatment technologies for each alternative, first water quality samples were analyzed to determine specific constituents of the Town's water, which are provided in a separate TM included as an attachment. Next, WTF manufacturers were engaged to provide proposals for each treatment facility alternative considered. Last, based on the proposals received, a capital cost and present worth analysis was completed for each alternative. This information was evaluated to inform the Town of the most economical approach to address water quality issues.

The Water Quality Sampling, Testing, and Data Analysis (Task 1C) memo indicates the Town's North Well exceeds the NPDWRs' MCLs for arsenic and turbidity and the NSDWRs' secondary standards for iron, sodium, and total dissolved solids (TDS), while the Town Wells exceed the NPDWRs' MCL for turbidity and the NSDWRs' secondary standards for aluminum, color, iron, manganese, odor, and sodium. A brief discussion on the Town's critical water constituents of concern follows.

#### Arsenic

Arsenic is a semi-metallic element that is odorless and tasteless. It enters drinking water sources from natural deposits in the earth or from agricultural and industrial practices. Arsenic is found naturally in the geological formations around Lakeview and much of southeastern Oregon. The MCLs established by the EPA's primary drinking water regulations for arsenic are 0.01 mg/L, or 10 parts per billion.

#### Manganese

Manganese is a naturally occurring mineral present in rocks, soil, groundwater, and surface water and is also found in most foods. Manganese is an essential nutrient, and eating a small amount daily is important for human health. The MCL established by the EPA's secondary guidelines for manganese is 0.05 mg/L. Manganese readings above the MCL may result in black to brown water color, staining, and a bitter metallic taste. Scott Langum September 9, 2022 Page -3-

#### Iron

Iron is also a naturally occurring mineral present in both nature and many foods. The MCL established by the EPA's secondary guidelines for iron is 0.3 mg/L. Iron readings above the MCL may result in rusty (red or orange) water color, staining, and a metallic taste. Sediment issues may also occur.

#### Aluminum

Aluminum is an abundant metal in the earth's crust that can leach from rock and soil to enter groundwater. The MCL established by the EPA's secondary guidelines for aluminum is 0.05 to 0.2 mg/L. Aluminum above the secondary MCL may result in gray colored water.

#### рΗ

The pH of water can affect treatment options, and a low pH can be corrosive to metal pipes in distribution systems and places of use. The MCL established by the EPA's secondary guidelines for pH is 6.5 to 8.5. Low pH may result in bitter metallic taste and corrosive properties. A high pH may result in deposits or a baking soda taste.

#### Sulfates and Hydrogen Sulfide

Sulfates and sulfur compounds occur naturally in rocks and soils. Under anaerobic conditions, sulfurreducing bacteria produce hydrogen sulfide by chemical reduction of dissolved sulfate. This process can occur both subsurface prior to pumping from the aquifer and/or within the water distribution itself between the treatment system and the end consumer. Sulfate and hydrogen sulfide are not regulated by the EPA. However, sulfate can add a bitter taste to water and have a laxative effect. Hydrogen sulfide is an unpalatable gas, which can create odor and taste issues.

#### **Regulatory Requirements**

Arsenic is a contaminant listed by the NPDWRs, which are outlined by the EPA as legally enforceable standards that apply to public water systems. The primary standards are used for public health protection by the limitation of specifically identified constituents. Iron, manganese, hydrogen sulfide, and aluminum are water quality parameters of the NSDWRs, which are non-enforceable guidelines for the outlined contaminants.

#### Water Treatment Technologies

Many treatment technologies are available to remove the contaminants present in the Town's water. To remove iron and manganese, oxidization of soluble forms of iron and manganese to insoluble forms followed by filtration is commonly used. Filtration of the oxidized precipitates can be achieved using either a synthetic membrane or filter media. Arsenic removal can be achieved with technologies including ion exchange, adsorption, coagulation and filtration, oxidation and filtration, or reverse osmosis. The oxidation/filtration process described above to remove iron and manganese can also be used to remove arsenic when adequate iron is present to facilitate the coprecipitation of the two. A brief description of the treatment technologies follows.

Scott Langum September 9, 2022 Page -4-

#### Ion Exchange

Ion exchange is a reversible reaction in which a charged ion in a solution is exchanged for a similarly charged ion electrostatically attached to an immobile solid particle. This exchange process replaces the unwanted ions with ions that do not degrade water quality. Within ion exchange, three types of resins can be utilized: cationic, anionic, and specialty. Cation resins can remove iron and manganese but not arsenic. If an anionic resin is utilized, arsenic can be removed from the water. The economy of ion exchange depends on water quality conditions. Ion exchange resins are susceptible to early fouling when high levels of nitrates, sulfates, TDS, and turbidity are present.

#### Adsorption

Another technology commonly used to remove arsenic from drinking water is adsorption. The process is similar to ion exchange in that the positively charged media is used to remove the negatively charged arsenic ions. Media replacement costs can become expensive due to reduced media life when certain constituents are present that compete for absorption sites or clog the media. Phosphate and silica have been shown to compete for adsorption sites on iron-based sorbents. Silica, iron, manganese, and sulfates compete for adsorption sites on activated alumina.

#### **Coagulation and Filtration**

Coagulation and filtration are processes in which a chemical additive is used to create precipitates in water. For example, arsenic naturally occurs as a fine particle that floats in water. However, when a coagulant such as ferric chloride is added to the water, the arsenic bonds with the ferric chloride, creating larger, heavier particles that can either be settled out by gravity or filtered. This technology's efficiency for removing arsenic can be highly affected by the pH of the water as well as the molecular form of arsenic present. Arsenate [As(V)] is readily adsorbed by most coagulants. However, arsenite [As(III)] is not, and preoxidation must be utilized to convert As(III) to As(V).

#### Oxidation, Precipitation, and Filtration

Oxidation is commonly used to convert soluble forms of iron and manganese to insoluble forms prior to filtration. Either chlorine or potassium permanganate is injected and mixed into the stream to oxidize iron, manganese, hydrogen sulfide, and arsenic. When a sufficient iron to arsenic ratio is present (usually 20:1), the coprecipitation of iron and arsenic occurs, and filtration effectively removes both constituents from the stream. Filtration can be achieved with pressure media filters or membranes. In both cases, the filters will become clogged as insoluble compounds are filtered, and periodic backwash cycles are needed to facilitate regeneration of the media or cleaning of the membrane. The backwash water is either disposed of or sent to a settling tank. After particulates settle, the clarified water (called supernatant) is recovered by returning to the beginning of the treatment facility while the concentrated sludge is disposed of.

Both the coagulation/filtration and oxidation/precipitation/filtration processes described above can utilize either membrane type or media type filtration technologies. These processes can also be combined to produce an oxidation/precipitation/coagulation/filtration process. Membrane filters physically separate particles larger than the membrane pore size, which are retained on the membrane surface. Media filters utilize a number of different media types including silica sand, Greensand Plus, and pyrolusite. In addition to oxidation by means of a chemical feed upstream of Scott Langum September 9, 2022 Page -5-

the filters, these media also oxidize iron and manganese in place on the media surface. Because of this ability, a lesser amount of oxidation by chemical injection can be achieved.

#### **Reverse Osmosis**

Reverse osmosis is a membrane separation process that removes contaminants from water. This process forces water at a high pressure through a semi-permeable membrane and retains various constituents based on their size, weight, and charge. Reverse osmosis produces product water and concentrate. Product water is the water with substances that were able to pass through the membrane. Concentrate is the constituents that are unwanted in the system.

#### **Treatment Facilities Alternatives**

As detailed in the 2019 WSMP, the Town Wells pump into a common transmission line that discharges into the Town's water storage tanks. The North Well is outside town limits and pumps into a water storage tank, independent of the other wells. The North Well requires arsenic treatment to meet water quality standards, while the Town Wells require the removal of iron and manganese. Combining the sources would require the removal of all three constituents. Aside from the actual type of treatment system to be utilized, two alternatives, referred to as Alternatives A and B, were considered.

Alternative A includes constructing separate treatment systems for the North Well and combined water of the Town Wells. The North Well treatment system would have a capacity of 400 gallons per minute (gpm) and be designed to only remove arsenic. The combined water central treatment system would have a capacity of 2,000 gpm and be designed to only remove iron and manganese.

Alternative B includes constructing a single centralized WTF designed to treat all combined water sources. The North Well would be connected to the Town Wells through a new 14,500 linear foot transmission line. The central treatment system would have a capacity of 2,400 gpm and be designed to remove arsenic, iron, and manganese. pH adjustment would be needed for this alternative to facilitate the coprecipitation of iron and arsenic.

During preparation of this TM, a third alternative, Alternative C, was discussed with the Town. Alternative C includes deferring use of the North Well, increasing the capacity of the Town Wells by 400 gpm to make up the difference lost by the North Well, and constructing a single combined water central treatment system with a capacity of 2,400 gpm. The WTF would be designed to remove iron and manganese only. By deferring use of the North Well, arsenic removal would not be required until such time that the North Well is brought back online.

The Town has already purchased a property that will be utilized for the central treatment facility included in Alternatives A, B, and C. The specific site for Alternative A's North Well WTF has not been determined or considered for this evaluation.

#### Manufacturer's Proposals

Six manufacturers were engaged to provide water treatment system proposals for Alternatives A and B. Five proposals were received. Alternative C was not considered until after proposals were received. Therefore, proposals were not received specifically for Alternative C. The manufacturers' type of proposed treatment system for each alternative are shown on Table 1. Scott Langum September 9, 2022 Page -6-

TABLE 1
MANUFACTURER PROPOSED TREATMENT SYSTEMS PER APPLICATION

ANTHRA - Anthracite

C/F - Treatment process utilizing coagulation and filtration

CCG - Continental Carbon Group

GSP - Greensand Plus media

O/C/P/F - Treatment process utilizing oxidation, coagulation, precipitation, and filtration

 ${\it O/P/F}$  - Treatment process utilizing oxidation, precipitation, and filtration

SIL - Silica sand

As shown on Table 1, various combinations of oxidation, coagulation, precipitation, and filtration were proposed by all manufacturers. Aside from Ovivo, the pressure vessel filtration systems proposed were similar in design, with some variation to the types and combinations of filter media, which included Greensand Plus, anthracite, and silica sand. Systems that included removing arsenic generally included the addition of a coagulant chemical feed system to aid in coprecipitation of iron and arsenic prior to removal. Ovivo was the only manufacturer to propose an alternative technology utilizing media filtration. CCG, Tonka Water, WesTech, and Wigen all proposed systems with similar cost, design, and operation, utilizing either vertical or horizontal pressure vessel filtration systems. AdEdge Technologies was contacted separately to consider the viability of an adsorption water treatment system. Due to water quality parameters and associated costs with replacing spent media, AdEdge responded that adsorption would not be a good candidate for this application.

All systems proposed above produce backwash water as a bioproduct of the treatment process. Backwash cycles continuously regenerate and clean filter media and membranes. Backwash water must either be disposed of or reclaimed through a settling tank and pump-assisted return line. Because the quantities of chemical feeds and backwash water produced have significant capital and life cycle costs, additional information was sought by the manufacturers regarding typical backwash and chemical feed rates. Scott Langum September 9, 2022 Page -7-

Another consideration of Alternative B is that the pH must be adjusted to less than 8.0 to facilitate the coprecipitation of iron and arsenic. Because the mixed well water associated with Alternative B has a pH greater than 8.0, the pH must be adjusted, ideally to 7.5. This operational consideration is discussed in more detail below. In contrast, lower pH significantly affects the oxidation rates of iron and manganese, creating further operational complications. These considerations in conjunction with the high cost of constructing the transmission line associated with Alternative B led to the development of Alternative C.

Figures 1 and 2 schematically show the treatment processes of pressure vessel media filtration and membrane filtration, respectively. Both systems show preceding oxidation and coagulation chemical feeds, and backwash reclaim systems. The need to utilize potassium permanganate as the oxidizing agent and use of coagulants may not be necessary if pilot studies demonstrate adequate removal utilizing only sodium hypochlorite. The primary difference between the systems is the physical means of filtration and regeneration and cleaning of media versus cleaning and scouring of the ceramic membranes. Figure 3 shows a typical site layout for either the 2,000 or 2,400 gpm treatment systems to be located on the Town's purchased property site.

#### Water Treatment System Life Cycle Cost Analysis

To determine the most economical water treatment approach for the Town, two cost analyses were developed for Alternatives A, B, and C. One analysis evaluates costs associated with using a membrane filtration technology, while the other evaluates costs associated with using a pressure vessel media filtration technology. Because the relative costs associated with pressure vessel media filtration were similar amongst the proposals received, the average cost of equipment and operational parameters were used to develop these analyses.

For this evaluation, the total capital cost and 20-year total present worth were evaluated under each option for each alternative. The total capital cost includes the procurement and installation of proposed equipment, and the manufacture and installation or construction of any additional ancillary facilities needed to provide the Town with a fully functional WTF. The costs include, but are not limited to, treatment equipment, buildings, backwash tanks, backwash sludge disposal facilities, and ancillary equipment and components.

The total present worth includes the total project cost as well as annual operation, maintenance, and replacements (OM&R) costs over a 20-year life cycle. These include, but are not limited to, labor, utilities, parts, sampling and testing, media replacement, chemical costs, and equipment replacement. Each system has different chemical feed rates. The values presented are preliminary based on manufacturer-provided best estimates for each system. For better accuracy, the dosing rates will be field-verified during a pilot program and associated costs will be adjusted prior to selection of the preferred system. Further detail is given below as to the primary considerations that affect costs with the various systems.

#### **Equipment and Building Costs**

Each proposed treatment system has different spatial requirements. This evaluation assumes the building needed to house treatment equipment will be a concrete masonry unit (CMU) structure with internal framing on a concrete slab foundation and reinforced concrete equipment pads as necessary. Pre-engineered steel frame structures may be considered to reduce capital costs, but CMU buildings are generally more robust and last longer than steel structures.

Scott Langum September 9, 2022 Page -8-

The water treatment building must be of sufficient size to house the treatment equipment, chemical feed stations, chemical storage, instrumentation and controls, and booster pumps, as well as any additional storage or office space the Town deems necessary for operations. The Town requested that the centralized treatment plant building should include four offices and a bathroom in addition to space needed for treatment and process equipment. An additional building footprint was included depending on the size of each manufacturer's proposed equipment. This generally includes the footprint of the equipment plus 10 feet on all sides for access and process piping connections. A 40 percent markup was applied to the manufacturer's budget proposal equipment costs for delivery and installation by the general contractor.

#### **Backwash Facilities**

Significant backwash volumes are produced at WTFs in most applications. Up to 95 percent of backwash volumes can be recovered and returned to the head end of the treatment plant. When backwash recovery facilities are not present, an increase in supply capacity results, which must be accounted for regarding source supply (installed pumping capacity) and maximum permitted water right withdrawal rates. Disposal of the backwash water must also be accounted for. Due to limited water rights, source capacity, and capacity of the existing wastewater collection and lagoon treatment systems to accept the backwash water volume and to promote water conservation, the Town should include backwash recovery facilities. Backwash facilities generally include backwash settling tanks, supernatant return lines with booster pumps, and sludge disposal facilities. The sludge disposal facilities consist of a lined evaporation pond, piping, and control structures. The pond surface area must be adequately sized to allow the liquid portion of the sludge disposed to evaporate. The pond storage volume must be adequate to store approximately two-thirds of the annual volume of sludge disposal. Backwash settling tanks should be sized for peak demand periods. Two tanks should be installed, each with the capacity to store the volume of one complete backwash cycle plus 15 percent.

Various water treatment systems and technologies produce different quantities of backwash water. Therefore, the cost associated with recycling backwash water for each individual system must be considered. Typical backwash volumes are best determined from pilot studies. Manufacturers can estimate backwash volumes based on water quality data for preliminary design purposes. Sizes of backwash tanks, pumps, and disposal facilities are based on estimated backwash volumes. This TM assumes preliminary backwash volumes provided with proposals received for evaluation purposes.

#### **Other Equipment and Construction Costs**

Costs common to all proposed treatment systems include backwash tank cathodic protection systems; mechanical; electrical; heating, ventilation, and air conditioning; plumbing work; chemical feed pumps and equipment; controls and instrumentation work; and standby power systems. The costs associated with this work are similar between various treatment systems with minor variations.

#### **Chemical Costs**

Water treatment requires various chemical feeds for the purposes of oxidation, coagulation, disinfection, facilitating media regeneration, and membrane cleaning when applicable. All proposed systems require oxidation of soluble forms of iron, manganese, and arsenic to insoluble forms. This

Scott Langum September 9, 2022 Page -9-

> is achieved by injecting either chlorine or potassium permanganate into the raw water stream. Chlorine is generally less expensive than potassium permanganate when used as an oxidizer, produces less quantities of sludge, and is easier to handle from an operational standpoint. Potassium permanganate may be needed if high chlorine feed rates result in disinfection byproducts, or when raw water pH is too low, which may result in an inadequate contact time for the oxidation of manganese. The use of potassium permanganate should be avoided if possible. Coagulation is needed for arsenic removal systems to facilitate coprecipitation of arsenic and iron. A pilot study will indicate which oxidizer will best suit the application and more accurately determine the anticipated chemical feed rates for each alternative.

#### Media Replacement Costs

Filter media will periodically require replacement as the media degenerates. Typically, this occurs every eight to ten years. Ovivo's ceramic membrane does not have media, but the membrane still needs to be inspected on a regular basis, and damaged membranes need to be replaced. Media replacement should be considered for life cycle present worth comparisons.

#### Total Capital Cost; Annual Operation, Maintenance, and Replacement; and Net Present Worth

To evaluate the most economical treatment system for the Town, two 20-year present worth analyses were completed for Alternatives A, B, and C. For each alternative, one present worth analysis assumes a membrane filtration technology is used, while the second assumes a media filtration is used. Total estimated construction costs include mobilization and furnishing and installing or constructing well and well pump station improvements, transmission lines, equipment, structures, backwash tanks, and sludge disposal evaporation ponds. Annual OM&R costs include labor, utilities, chemicals, filter media replacement (when applicable), and equipment replacement.

Table 2 presents the total estimated construction cost, total annual OM&R cost, and 20-year total present worth for each alternative. See Figures 4 through 9 for detailed cost estimates for each alternative option shown on Table 2.

Type of	Total Estimated Construction	Total annual OM&R	Total Present Worth						
Filtration	Cost (2022 Dollars)	(5 percent, 20 years)	(2022 Dollars)						
Alternative A									
Membrane	\$13.3 million	\$820,000	\$23.5 million						
Media	\$13.4 million	\$680,000	\$21.9 million						
Alternative B									
Membrane	\$13.3 million	\$540,000	\$19.9 million						
Media	\$14.1 million	\$450,000	\$19.7 million						
	Alternative C								
Membrane	\$10.4 million	\$510,000	\$16.8 million						
Media	\$11.2 million	\$430,000	\$16.6 million						

 TABLE 2

 TREATMENT TECHNOLOGY TOTAL PRESENT WORTH COMPARISON

As shown on Table 2, Alternative A is the most expensive option for both capital costs and annual OM&R, and Alternative C is the least expensive option for both capital costs and annual OM&R. For each alternative, the capital cost associated with utilizing a membrane filtration technology is lower than with

Scott Langum September 9, 2022 Page -10-

a media filtration type technology, but the annual OM&R is higher. Relatively speaking, the total present worth of utilizing a membrane filtration technology is similar to that of a media filtration type technology.

In comparison to pressure vessel media type filtration systems, membrane filtration will require more operator skill and attention. Membrane filtration will also require a greater number of chemical feeds, which further increases operator skill and attention. The primary disadvantage to Alternative A is that the Town would have to operate and maintain two WTFs compared with only a single facility for Alternatives B and C. The primary disadvantage to Alternative B is that to removal iron, manganese, and arsenic with a single system, the pH would need to be adjusted, which further increases chemical costs and operator skill and attention. Advantages of Alternative C in comparison to Alternatives A and B include, but are not limited to:

- Only a single combined water central treatment system is needed.
- Necessary improvements to the North Well Pump Station and construction of a new transmission line is removed from the cost of Alternative B.
- Neither ferric chloride nor pH adjustment is needed, effectively removing two chemical feed processes from the system, and reducing operator skill and attention.
- The system will create less backwash water and sludge in comparison to the other alternatives.

Based on a capital cost and net present worth analysis, it is recommended that the Town select Alternative C. The viability of this alternative must be confirmed with further investigation. If it is found that Alternative C is not viable due to limited source capacity and/or water rights, it is recommended that the Town select Alternative B.

#### Recommended Treatment Technology

Based on the information gathered, the recommended treatment technology for all alternatives is oxidation and filtration. Coagulation will be needed if the North Well is to be brought back online. Filtration by silica sand, Greensand Plus, or pyrolusite media is the likely candidate for this application. Membrane filtration may be considered; however, Ovivo, which was the only manufacturer to propose such a system, was unable to provide examples of similar installations using the proposed technology in the U.S. Without having examples of a proposed technology's implementation and success, it is not recommended the Town select such a system.

#### Conceptual Discussion of the Viability of Alternative C

Due to the high cost of treating the North Well for arsenic, or alternatively, piping the North Well to the central treatment facility with a transmission line and other upgrades, increasing the capacity of other Town Wells by 400 gpm was evaluated to preliminarily consider the viability of Alternative C. For each well, Table 3 shows the current installed pump capacity, current water right maximum withdrawal rate, initial yield during original construction, drawdown during initial yield test, and approximate pump setting below ground surface (BGS). Table 3 was used to determine if increasing the capacity of any combination of the Town's wells is a viable solution if the North Well is abandoned.

Scott Langum September 9, 2022 Page -11-

Well ID <sup>1</sup>	Existing Pumping Capacity	Maximum Permitted Withdrawal Rate (gpm)	Initial Yield (gpm)	Drawdown (feet BGS)	Maximum Potential Yield <sup>2</sup> (gpm)	Water Quality
Well No. 2	550	0	500	N/A	N/A	Poor
Well No. 6	500	750	800	75	1,300	Poor
Well No. 7	550	600	1,200	55	2,500	Fair
Well No. 8	0 <sup>3</sup>	350	350	181	300	Fair
Well No. 9	500	1,125	750	135	1,100	Poor
North Well	700	400				Poor

TABLE 3 CONCEPTUAL SOURCE CAPACITY EVALUATION

<sup>1</sup>Well No. 1 is abandoned; therefore it is not included herein.

<sup>2</sup>Based on the measured specific capacity assuming pumping drawdown to 150 feet from the bottom of well as shown on the Oregon well log.

<sup>3</sup>Well No. 8 is currently plugged.

N/A = not applicable

As shown on Table 3, if the existing pumping capacities of Wells No. 6, 7, and 9 were increased to their maximum permitted withdrawal rates, the sources could supply the Town with the 2,400 gpm needed to meet the 2019 WSMP planning year's maximum daily demand. Due to the age of the wells, well and aquifer drawdown tests will be needed to confirm each well's ability to produce these rates before the viability of this alternative is confirmed.

#### **Recommended Approach**

The detailed design of a WTF depends heavily on the technology and specific equipment selected. The total building footprint, installation of process piping and ancillary equipment, backwash reclamation facilities, and sludge disposal facilities all depend on treatment performance, which differs between manufacturers and the type of media selected. To properly design a fully functional WTF, a specific manufacturer and type of media must be selected for use as the basis of final full-scale design. Additionally, the exact treatment efficiency cannot be precisely determined until a pilot study is performed. Because pilot studies are specific to a manufacturer's specific equipment, no single pilot study can guarantee the performance of various systems.

If a single manufacturer is selected for use as the basis of design prior to purchasing the equipment, the Town would lose the benefit of a competitive bid on equipment, and the selected manufacturer may use this to their advantage, increasing the cost of proposed equipment. To maintain the competitive bid process, it is recommended the Town of Lakeview issue a request for proposals (RFP) to solicit proposals from equipment vendors with the intent to select a preferred water treatment equipment package and pre-purchase and procure said package. The RFP would include contract documents and the technical specifications necessary for each equipment vendor to submit a proposal to the Town. Proposals should include, but not be limited to, the proposed equipment's installed footprint, cost, anticipated range of backwash volume and frequency, anticipated chemical feed rates, anticipated media replacement frequency and cost, range of operational flexibility (minimum and maximum flux rates), and list of similar installations. The proposal requirements will also include the design, delivery, set up and operation of a pilot study for the selected package to document and confirm that the proposed package

Scott Langum September 9, 2022 Page -12-

will effectively and efficiently treat the Town's water prior to moving forward with the full purchase of the package and 30 percent design.

Each RFP will be evaluated using a scoring matrix and weighted ranking criteria. Each RFP will be weighted on the equipment package and delivery cost, pilot study cost, operational flexibility, number of similar installations, required operator skill and attention, and annual chemical costs. The selected vendor will be required to complete a pilot study to confirm treatment performance. If the pilot study fails to meet performance indicated in the RFP, the Town will be given the option to consider other systems at no cost. If the pilot study confirms treatment performance but the Town decides not to select the equipment for other reasons, the Town will be responsible for the cost of the pilot study. The pre-purchased equipment package would then be used as basis of design for the full-scale WTF detailed design, and the selected vendor would be required to provide a process guarantee and bond to the Town as part of the purchase price and agreement. Upon completion and approval of the final design, the overall Water System Improvements project will be put out to bid using a competitive public bid process while the pre-purchased equipment is procured. The awarded contract for the Water System Improvements project will be town's pre-purchased treatment equipment package by the contractor.

The advantage for the Town of using this approach is that it retains the competitive bid process for the equipment and delivery costs, while allowing the Town to proceed with a final full-scale design of the WTF designed around the selected equipment. Due to long delivery times from disruptions to current supply chains, another advantage for this approach is that the equipment delivery time frame can coincide with detailed design and bidding of the other project elements. This process would expedite system construction and commissioning of the WTF.

#### Summary

The purpose of this TM was to evaluate various treatment technologies and proposals received by manufacturers for equipment necessary to remove iron, manganese, and arsenic from the Town's drinking water and to inform the Town of the most economical alternative. The original scope of work included evaluation of two alternatives. Alternative A included installing one WTF to remove arsenic from the North Well, and a separate central WTF to remove iron and manganese from the Town Wells. Alternative B included the installation of a transmission line from the North Well to the Town Wells, and installing a single combined water central treatment system to remove iron, manganese, and arsenic from the combined water. Alternative C was proposed during the preparation of this TM and includes deferring use of the North Well, increasing the capacity of the Town Wells, and installing a single combined water central treatment or remove iron and manganese.

After review of the Town's water quality constituents and treatment system proposals received, it was determined that pressure vessel filters with either a Greensand Plus or pyrolusite media is the best candidate for any installation associated with the three alternatives. Proposals received for this equipment were similar in cost, application, and operation. However, some variations to anticipated backwash water quantities and chemical feed rates were received. Vendors stated in all cases that actual performance efficiency must be verified with a pilot study.

Treatment performance efficiency directly effects the size of facilities needed to provide the Town with a fully operational treatment system. Therefore, a pilot study of selected equipment must be completed to confirm performance, backwash rates and volumes, chemicals needed, and chemical feed

Scott Langum September 9, 2022 Page -13-

rates, which will then be used as the basis of design for the full-scale WTF. During the preparation of this TM, the Town decided to solicit as an RFP from treatment equipment vendors to select, pre-purchase, and procure equipment to use as the basis of design for the final design. The vendor will be required to verify treatment performance of the proposed equipment prior to the purchase.

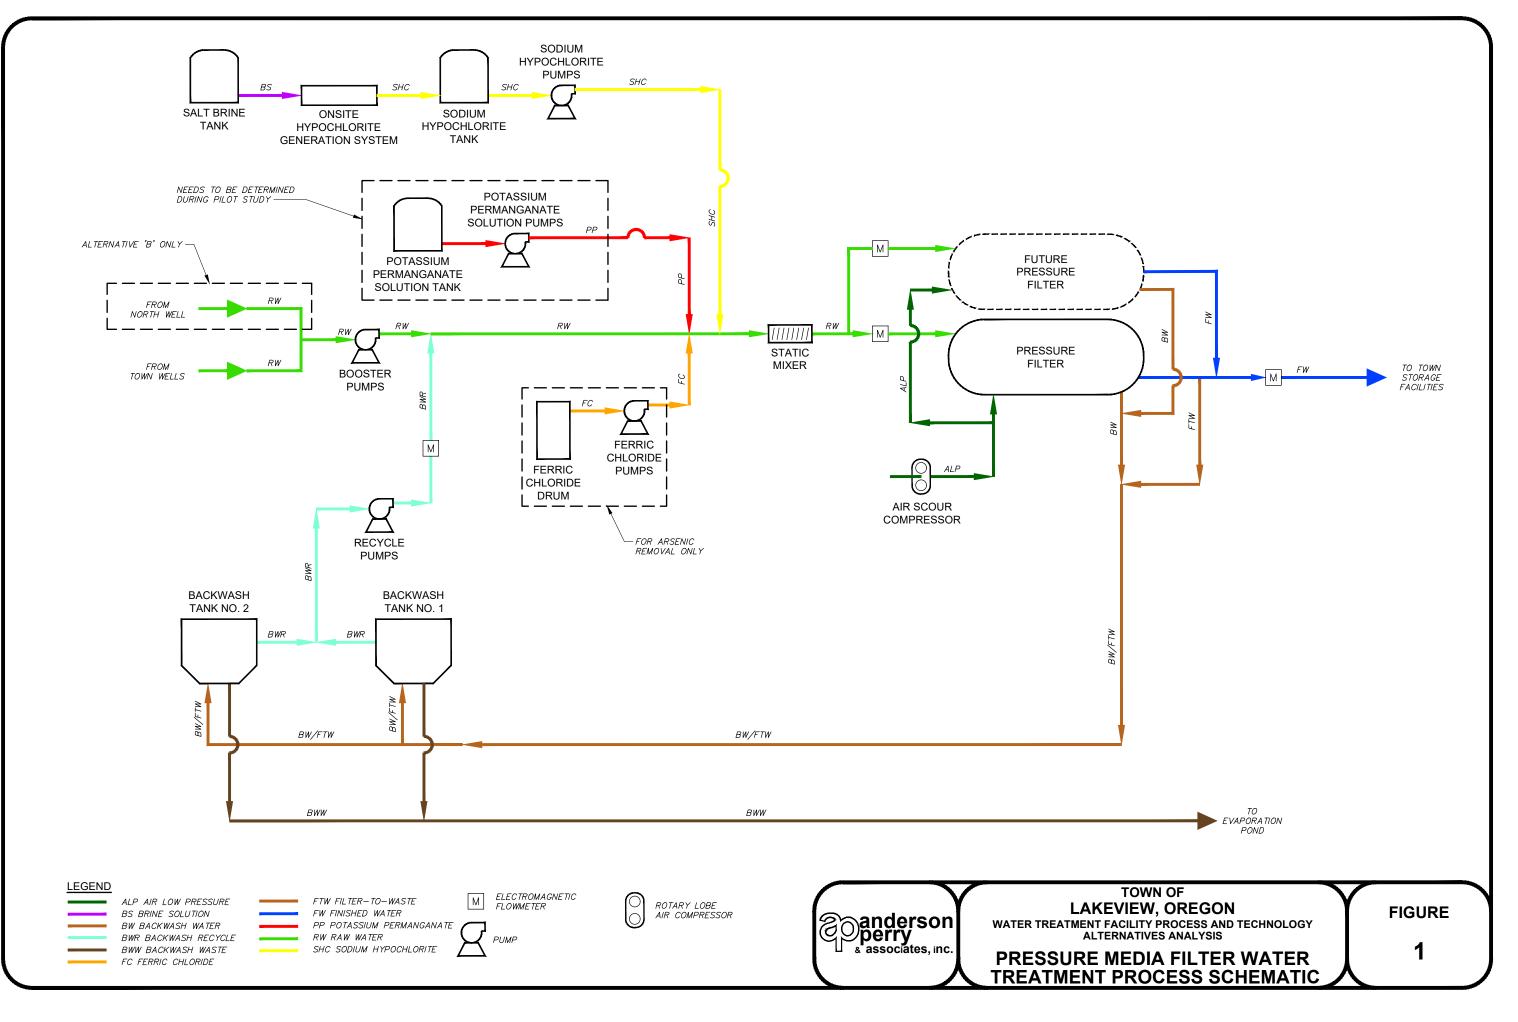

After review of the alternatives and net present worth analysis, the Town decided that Alternative C is preferred. The preliminary analysis as presented herein shows that this alternative is likely viable. The design flows will be reevaluated during preliminary design. The maximum treatment capacity of 2,400 gpm was determined by the 2019 WSMP and includes anticipated flows by a new Red Rock Biofuels facility, which was anticipated to go online in 2020. The Red Rock Biofuels facility has yet to break ground and precise water demands by the facility are currently uncertain. The Town is considering installing only enough treatment to meet the Town's 20-year projected capacity without the Red Rock Biofuels facility but provide adequate space within the facilities to expand treatment if necessary. This would include installation of a WTF capable of treating up to 1,700 gpm, with adequate space and ancillary facilities designed to accommodate treatment up to 2,400 gpm.

## ATTACHMENT Water Quality Sampling, Testing, and Data Analysis (Task 1C) Technical Memorandum

engineering • surveying • natural resources

# **TECHNICAL MEMORANDUM**

То:	Scott Langum, Town of Lakeview	
From:	Troy Baker, P.E.	
Subject:	Water Quality Sampling, Testing, and Data Analysis (Task 1C)	MERED PROFESO
Date:	July 15, 2022	GINE A 65318PE
Job/File No.	214-01-24.1 (w/encl.)	
cc:	Michele Parry, Town of Lakeview Dan Scalas, P.E., Adkins Engineering Amber Hudspeth, Hudspeth Land+Water (HLW) Jeremy Wenger, P.E., Fluent Engineering Tawni Bean, Business Oregon Larry Holzgang, Business Oregon Lucas Stangel, P.E., Anderson Perry & Associates, Inc. (AP) Bryce Wininger, P.E., AP Austin Byrer, AP	Digitally Signed OREGON AMA. 12, 2001 FOF L. BAN RENEWS 12-31-23

#### Introduction

The purpose of this technical memorandum is to summarize the results of the water quality testing and data analysis for the Town of Lakeview, Oregon's existing water sources. Water quality results provided to AP will help identify water treatment technologies suited for the Town's water quality and provide data to assist with selection of the most appropriate and cost-effective treatment process for the Town's water system improvements (WSI). Under the Professional Services Agreement dated March 9, 2022, the Town hired AP to complete engineering services related to the WSI including summarizing the results of the water samples collected from the Town's existing water sources. Water quality data have been summarized to better evaluate treatment technologies available for the Town. The water quality data summarized were obtained from the reported water quality sampling and testing data provided by independent laboratories. Constituents included in the water quality sampling and testing data are based on the 2018 Water System Master Plan (WSMP) and the Environmental Protection Agency's (EPA) primary and secondary drinking water standards.

The EPA outlines various constituents that can be found in municipal water systems. The EPA has two categories of constituents, primary and secondary drinking water standards, which set limits for each constituent. Primary drinking water standards are legally enforceable contaminant limits established to help protect the health and safety of municipal water system consumers. Secondary drinking water standards are non-enforceable contaminant limits considered to affect taste, odor, and cosmetic qualities of the water and are not necessarily related to protecting the health and safety of consumers.

Sound Solutions

Solid Engineering

Scott Langum July 15, 2022 Page -2-

#### **Testing and Sampling Method**

The reported water quality data were derived from water samples collected and packaged by HLW. The water samples were then sent by HLW to Brooks Applied Labs (BAL) and Edge Analytical to test for various water quality constituents. The samples provided to BAL and Edge Analytical were grab samples taken from each existing water source. Grab samples are a single sample collected in an individual container from a specific site to use for testing purposes. They represent an instantaneous sample of water quality constituents found in the associated water source the sample was taken from.

Testing methods performed by both laboratories are shown next to each constituent under the method column in the data reports included in the appendices. Testing methods performed by laboratories for drinking water samples use EPA-approved methods. The definition of each EPA-approved testing method is described on Table 1.

TESTING METHODS AND METHOD DESCRIPTIONS						
Testing Method	Method Description					
EPA Method 100.2	Determines the presence and quantifies the number of asbestos structures					
	longer than 10 micrometers in drinking water samples.					
EPA Method 200.8	Determines 21 elements shown as dissolved elements in drinking water					
	samples, with organometallic compounds determined as total metals.					
Method OIA-1677-DW	Determines the available cyanide in drinking water.					
EPA Method 300.0	Determines common inorganic anions in drinking water, and a secondary					
	part determines bromate, chlorate, and chlorite in drinking water.					
EPA Method 200.7	Determines 31 analytes in the dissolved fraction of aqueous samples and					
	total recoverable analytes in water.					
EPA Method 180.1	Determines the nephelometric turbidity units (NTUs) in drinking water.					
EPA Method 900.0	Determines the measurement of gross alpha and beta particle activities in					
	drinking water utilizing a screening technique.					
EPA Method 903.1	Determines the measurement of radium-226 in drinking water.					
EPA Method 904.0	Determines the beta activity from actinium-228 produced by decaying					
	radium-228; can be related to the radium-228 present in the sample.					
EPA Method 245.1	Determines the mercury in drinking water.					
EPA Method 548.1	Determines the endothall in drinking water.					
EPA Method 549.2	Determines the diquat and paraquat in drinking water.					
EPA Method 524.2	Determines the purgeable volatile organic compounds and some					
	disinfection byproducts in drinking water.					
IC-ICP-CRC-MS	Determines arsenic speciation in drinking water.					

TABLE 1 TESTING METHODS AND METHOD DESCRIPTIONS

BAL provided arsenic speciation testing for the North Well. This testing was analyzed on May 17, 2022, and the testing results were provided on May 19, 2022. The remaining constituents summarized on Table 2 were taken from each water source during two independent grab sample events and tested by Edge Analytical. Edge Analytical provided testing for the North Well; Wells No. 2, 6, 7, and 9; and the Spring Line. Testing results were provided by Edge Analytical on February 2, 2022, and May 27, 2022, for the first and second set of sampling events, respectively.

Scott Langum July 15, 2022 Page -3-

#### Water Quality Data

The following water quality data on Table 2 provide a summary of testing results associated with samples obtained from the Town's existing water sources and tested by BAL and Edge Analytical. The regulatory EPA limits for constituents are also provided on Table 2 for reference. Constituents included on the summarized table are a combination of primary and secondary drinking water standards established by the EPA as well as constituents of interest outlined in the WSMP and scope of work. Two of the Town's existing water sources were not included on Table 2; Well No. 8 and the Spring Line. Well No. 8 was not included, as the well is not currently producing water. The Spring Line was not included as it is not a consistent water source available for the Town year-round, and it is not the intent to treat water from the spring source through the new treatment facility.

Primary EPA Constituents	North	Well	Well	Well	Well	EPA

TABLE 2 WATER QUALITY DATA

A blank EPA limit cell indicates a level is not currently established; however, the constituent is important in identifying appropriate treatment technologies. EPA limits for arsenic are only specified for total arsenic.

Scott Langum July 15, 2022 Page -4-

<sup>1</sup> No more than 5.0 percent of samples collected in a month may be total coliform positive. For water systems that collect fewer than 40 routine samples per month, no more than one sample can be total coliform positive per month.

CFU = colony-forming units mg CaCO<sub>3</sub>/L = milligrams per liter as calcium carbonate mg/L = milligrams per liter N/A = not applicable ND = not detected NTU = nephelometric turbidity units TDS = Total Dissolved Solids

#### Conclusion

As shown on Table 2, the Town of Lakeview has water quality issues that need to be addressed to meet EPA limits and to provide aesthetically pleasing water for residents. Arsenic is the main constituent within the Town's water sources that has an EPA primary standard above the enforceable limit. High levels of aluminum, iron, manganese, and TDS all are EPA secondary standards identified as contaminants that may account for colored water and taste issues. Other constituents, such as pH or sulfate, may affect how treatment of the water is achieved, which will help determine the treatment technology required for the Town's needs. It is important to note that the water quality data analyzed were from a small sample set of water quality data; therefore, the higher constituent value between the two testing results was used. This allows for a conservative estimate when determining an appropriate treatment technology. The Water Treatment Facility Process and Technology Alternatives Analysis technical memorandum provided as Task 1D will outline additional information and analysis with respect to water quality, explore available treatment technologies, and outline the technology recommended for and selected by the Town. For additional sampled and tested constituents, refer to Appendix A for the BAL testing report, Appendix B for the Edge Analytical Report from February 2, 2022, and Appendix C for the Edge Analytical Report from May 27, 2022.

### APPENDIX A BROOKS APPLIED LABS TESTING REPORT

May 19, 2022

Hudspeth Land and Water, LLC ATTN: Amber L. Hudspeth 7485 SW Joshua Court Powell Butte, Oregon 97753 amber@hlworegon.com

RE: Project HUD-BD2201

**Client Project: Drinking Water** 

Dear Amber L. Hudspeth,

On May 11, 2022, Brooks Applied Labs (BAL) received one (1) water sample. The sample was loggedin for the analyses of Arsenic Speciation (arsenite [As(III)], arsenate [As(V)], monomethylarsonic acid [*MMAs*], dimethylarsinic acid [*DMAs*], and unknown arsenic species) according to the chain-of-custody form. All samples were received and stored according to BAL SOPs and EPA methodology.

The sample was field filtered by the client.

#### Arsenic Speciation Quantitation by IC-ICP-CRC-MS

Arsenic speciation was performed by ion chromatography inductively coupled plasma collision reaction cell mass spectrometry (IC-ICP-CRC-MS). Arsenic species are first chromatographically separated on an ion exchange column and then quantified using inductively coupled plasma collision reaction cell mass spectrometry (ICP-CRC-MS). For more information on this determinative technique, please visit the Interference Reduction Technology section on our website.

In instances where the native sample result and/or the associated duplicate (DUP) result were below the MDL the RPD was not calculated (N/C).

It should be noted that all Brooks Applied Labs, LLC methods, standard operating procedures, inventions, ideas, processes, improvements, designs, and techniques included or referred to therein, must be considered and treated as Proprietary Information, protected by the Washington State Trade Secret Act, RCW 19.108 et seq., and other laws. All Proprietary Information, written or implied, will not be distributed, copied, or altered in any fashion without prior written consent from Brooks Applied Labs, LLC. All Proprietary Information (including originals, copies, summaries, or other reproductions thereof) shall remain the property of Brooks Applied Labs, LLC at all times and must be returned upon demand. Furthermore, products presented in this document may be protected by Federal Patent laws and infringement will be subject to prosecution in accordance with Title 35 US Code 271.

The results were not method blank corrected, as described in the calculations section of the relevant BAL SOP(s), and were evaluated using reporting limits adjusted to account for sample aliquot size. Please refer to the *Sample Results* page for sample-specific MDLs, MRLs, and other details.

All data was reported without further qualification and all other associated quality control sample results met the acceptance criteria.

BAL, an accredited laboratory, certifies that the reported results of all analyses for which BAL is NELAP accredited meet all NELAP requirements. For more information please see the *Report Information* page in your report. This report should be used in its entirety for interpretation of results.

Please feel free to contact us if you have any questions regarding this report.

Sincerely,

Amy foodalf

Amy Goodall Project Manager Brooks Applied Labs amy@brooksapplied.com

#### Laboratory Accreditation

BAL is accredited by the *National Environmental Laboratory Accreditation Program* (NELAP) through the State of Florida Department of Health, Bureau of Laboratories (E87982) and is certified to perform many environmental analyses. BAL is also certified by many other states to perform environmental analyses. For a current list of our accreditations/certifications, please visit our website at <<u>http://www.brooksapplied.com/resources/certificates-permits</u> or review Tables 1 and 2 in our Accreditation Information. Results reported relate only to the samples listed in the report.

#### **Field Quality Control Samples**

Please be notified that certain EPA methods require the collection of field quality control samples of an appropriate type and frequency; failure to do so is considered a deviation from some methods and for compliance purposes should only be done with the approval of regulatory authorities. Please see the specific EPA methods for details regarding required field quality control samples.

#### **Common Abbreviations**

AR	as received	MS	matrix spike
BAL	Brooks Applied Labs	MSD	matrix spike duplicate
BLK	method blank	ND	non-detect
BS	blank spike	NR	non-reportable
CAL	calibration standard	N/C	not calculated
ССВ	continuing calibration blank	PS	post preparation spike
CCV	continuing calibration verification	REC	percent recovery
COC	chain of custody record	RPD	relative percent difference
D	dissolved fraction	SCV	secondary calibration verification
DUP	duplicate	SOP	standard operating procedure
IBL	instrument blank	SRM	reference material
ICV	initial calibration verification	Т	total fraction
MDL	method detection limit	TR	total recoverable fraction
MRL	method reporting limit		

#### **Definition of Data Qualifiers**

(Effective 3/23/2020)

- **E** An estimated value due to the presence of interferences. A full explanation is presented in the narrative.
- **H** Holding time and/or preservation requirements not met. Please see narrative for explanation.
- J Detected by the instrument, the result is > the MDL but  $\leq$  the MRL. Result is reported and considered an estimate.
- J-1 Estimated value. A full explanation is presented in the narrative.
- M Duplicate precision (RPD) was not within acceptance criteria. Please see narrative for explanation.
- N Spike recovery was not within acceptance criteria. Please see narrative for explanation.
- **R** Rejected, unusable value. A full explanation is presented in the narrative.
- U Result is ≤ the MDL or client requested reporting limit (CRRL). Result reported as the MDL or CRRL.
- **X** Result is not BLK-corrected and is within 10x the absolute value of the highest detectable BLK in the batch. Result is estimated.
- **Z** Holding time and/or preservation requirements not established for this method; however, BAL recommendations for holding time were not followed. Please see narrative for explanation.

These qualifiers are based on those previously utilized by Brooks Applied Labs, those found in the EPA <u>SOW ILM03.0</u>, Exhibit B, Section III, pg. B-18, and the <u>USEPA Contract Laboratory Program National Functional Guidelines for Inorganic</u> <u>Superfund Data Review; USEPA; January 2010</u>. These supersede all previous qualifiers ever employed by BAL.

### Accreditation Information
